

Text as Data: Homework 5

Jeff Ziegler

August 23, 2017

1 Using the Structural Topic Model in R

Using the preprocessed data based on the NYT Json file and the subsequent document term matrix for analysis in `stm`.

- a) Download the `stm` package for R from CRAN
- b) Convert the document-term matrix to the appropriate format. To do this, create a list in R where each component of the list corresponds to an individual document. Store in each component of the list a two row matrix. The number of columns corresponds to the number of non-zero entries for the document in the document-term matrix. The first row will describe the words used in the document (the columns with the non-zero entry). The second row will correspond to a count of each of the words in the document (they should all be non-zero)
- c) Following the help file in `STM` fit a model with 8 topics that conditions on the `desk` of origin for topic prevalence
- d) Use `labelTopics` to label each of the topics
- e) Compare the 8 topic proportions for each document to the 8 topic proportions without conditioning on `desk` (in vanilla LDA). How do the results differ?

```
1 # Problem 1
2
3 # load libraries and .csv files
4 library(rjson); library(stm); library(tm); library(stringr)
5 NYTjson <- fromJSON(file=~ /Documents/Git/WUSTL-textAnalysis/nyt-ac.json")
6
7 # fit a model with 8 topics that conditions on the desk of origin
8 # prep documents for STM
9 stmData <- as.data.frame(cbind(sapply(lapply(NYTjson, '[', c('meta', 'dsk'))),
10                                paste0, collapse=""),
11                           sapply(lapply(NYTjson, '[', c('body', 'body_
12                                text')), paste0, collapse=""))
```

```

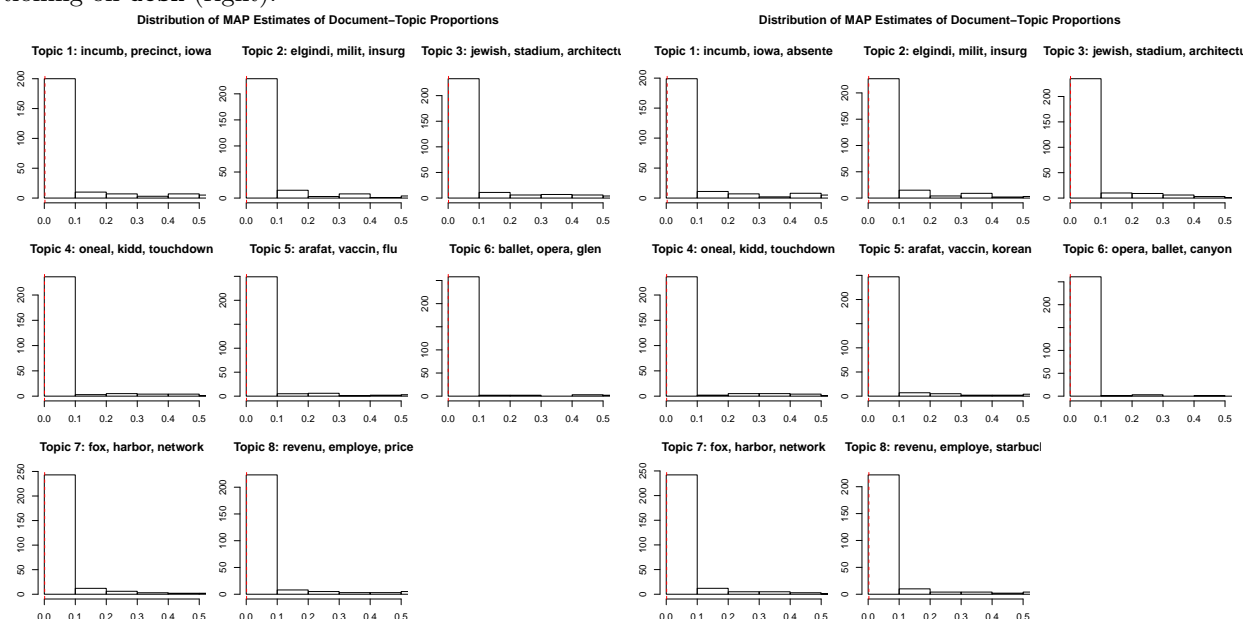

11 names(stmData) <- c("desk", "documents"); stmData$documents <- as.character(
    stmData$documents)
12 # create a function to only take first 25 words to preview docs
13 # visualize labels
14 makeShortDoc <- function(x) {
15   ul = unlist(strsplit(x, split = "\\s+"))[1:25]
16   paste(ul, collapse=" ")
17 }
18 stmData$shortdoc <- unlist(lapply(stmData$documents, makeShortDoc))
19
20 #stmData$desk <- as.factor(stmData$desk)
21 processedSTM <- textProcessor(stmData$documents, metadata = stmData)
22 outSTM <- prepDocuments(processedSTM$documents, processedSTM$vocab,
    processedSTM$meta)
23
24 # fit STM w/ 8 topics
25 # using the default settings found in the help package
26 stmModel <- stm(documents = outSTM$documents, vocab = outSTM$vocab, K = 8,
27   prevalence = ~desk, max.em.its = 75, data = outSTM$meta,
28   init.type = "Spectral")
29
30 # d) label each topic
31 labelTopics(stmModel, c(1:8))
32
33 # create visualization of topics by previewing docs
34 pdf("~/Documents/Git/WUSIL_textAnalysis/HW5topicReview.pdf")
35 par(mfrow = c(2, 4), mar = c(.5, .5, 1, .5))
36 for(i in 1:8){
37   plotQuote(findThoughts(stmModel, texts = stmData$shortdoc, n = 2, topics = i
    )$docs[[1]],
38     width = 30, main = paste0("Topic", i, sep=" "))
39 }
40 dev.off()
41
42 # e) run vanilla LDA
43 # using the default settings found in the help package
44 ldaModel <- stm(documents = outSTM$documents, vocab = outSTM$vocab, K = 8,
45   max.em.its = 75, data = outSTM$meta, init.type = "Spectral")
46 # plot LDA and STM topic proportions
47 pdf("~/Documents/Git/WUSIL_textAnalysis/HW5topicProportionsSTM.pdf")
48 plot(stmModel, type = "hist", xlim = c(0, .5), labeltype="frex")
49 dev.off()
50
51 pdf("~/Documents/Git/WUSIL_textAnalysis/HW5topicProportionsLDA.pdf")
52 plot(ldaModel, type = "hist", xlim = c(0, .5), labeltype="frex")
53 dev.off()
54 # not much difference between the two estimated topic proportions

```

2 Machiavelli's Prince

In this part of the assignment we will analyze Machiavelli's *The Prince*. Download **Mach.tar** from the course website and expand the compressed folder. (This is relevant <http://xkcd.com/1168/>).

Each file represents a subset of the manuscript. We will analyze its contents using principal components, multidimensional scaling, and clustering methods.

Create a Document-Term Matrix

Using the sections from the Machiavelli text, create a document term matrix.

- Discard punctuation, capitalization
- Apply the porter stemmer to the documents
- Identify the 500 most common unigrams
- Create a $N \times 500$ document term matrix \mathbf{X} , where the columns count the unigrams and the rows are the documents

We will work with a normalized version of the term document matrix. That is we will divide each row by the total number of words in the top 500 unigrams used:

$$\mathbf{x}_i^* = \frac{\mathbf{x}_i}{\sum_{j=1}^{500} x_{ij}}$$

$$\mathbf{X}^* = \begin{pmatrix} \mathbf{x}_1^* \\ \mathbf{x}_2^* \\ \vdots \\ \mathbf{x}_N^* \end{pmatrix}$$

```

1 # Problem 2
2
3 # we'll make our DIM using the tm package primarily
4 # create a corpus and transform data
5 # read in files
6 # make corpus
7 machText <- Corpus(DirSource("~/Documents/Git/WUSTL_textAnalysis/MachText"),
8                     readerControl = list(language = "en"))
9 # remove punctuation and capitalization
10 machText <- tm_map(machText, removePunctuation)
11 machText <- tm_map(machText, content_transformer(tolower))
12 # we'll also remove stop words
13 machText <- tm_map(machText, removeWords, stopwords("english"))
14 # apply porter stemmer
15 machText <- tm_map(machText, stemDocument)
16 # create DIM of machTexts
17 machDTM <- DocumentTermMatrix(machText)
18 # reduce DIM to top 500 unigrams
19 machDTM <- machDTM[, c(501:2367)]
20 # normalize by term frequency - i.e. divide count of each word
21 # in document by total number of words in document
22 machDTM <- normalize(machDTM$j)
23
24 # reduce DIM to top 500 unigrams
25 machDTM <- machDTM[, c(501:2367)]
26 # show top 500 unigrams
27 # machDTM$dimnames$Terms
28 # see what DIM looks like
29 machDTM <- machDTM/rowSums(as.matrix(machDTM))
30 inspect(machDTM)

```

```

<<DocumentTermMatrix (documents: 188, terms: 500)>>

Low Dimensional Embeddings with Principal Components

- 1) Wise Will (WW), your friend with a weird name, notices you looking at the slides about principal component analysis (PCA). WW casually remarks that the variance of the eigenvalues of the variance-covariance matrix is a useful heuristic for knowing if PCA can be fruitfully applied to some document-term matrix. WW, completely unsolicited, explains that as the variance of the eigenvalues goes up, the more useful PCA will be. He then laughs and leaves your office. WW is kind of a jerk.

Let's formalize WW's suggestion. Suppose document-term matrix \mathbf{X} has variance-covariance matrix $\mathbf{\Sigma} = \frac{\mathbf{X}'\mathbf{X}}{N}$. And suppose that $\mathbf{\Sigma}$ has eigenvalues $\lambda_1 > \lambda_2 > \dots > \lambda_d > 0$. Then we calculate the variance of the eigenvalues as

$$\sigma^2 = \frac{1}{d} \sum_{j=1}^d (\lambda_j - \bar{\lambda})^2$$

where $\bar{\lambda}$ is $\frac{1}{d} \sum_{i=1}^d \lambda_i$. WW is saying that as σ^2 gets bigger, a low-dimensional embedding via PCA will provide a better summary of our data.

Does WW have a good point? Why or why not? (Hint: what do the eigenvalues represent?)

Reducing the variance of the eigenvalues may or may not help improve PCA's ability to better summarize data, but reducing the sum of remaining eigenvalues reduces the error because the total variance explained = (sum of included eigenvalues)/(sum of all eigenvalues).

- 2) Apply the function `prcomp` to \mathbf{X}^* . Be sure to set use a scaled version of the data, by setting `scale = T`, which will ensure that each column has unit variance.

- a) Create a plot of variance explained by each additional principal component. What does this plot suggest about the number of components to include?
- b) Plot the two-dimensional embedding of the text documents. Label the texts with their number. (Each file is `Mach_XX.txt`, where `XX` is the chunk number)
- c) Label the two largest principal components. What does this embedding suggest about the primary variation this representation of the Prince? (Hint: if your `embed` is your object with principal components, examine `embed$rotation`)

```

1 # Problem 3
2
3 # 2) apply the function prcomp
4 # scale data to ensure each column has unit variance
5 machPCA <- prcomp(machDTM, scale = T)
6
7 # a ) reate a plot of variance explained by each additional principal
  component
8 pdf("~/Documents/Git/WUSIL_textAnalysis/HW5screePlot.pdf")
9 plot(machPCA, type = "l")
10 dev.off()
11 # the "elbow rule" doesn't really apply, and we don't want to introduce
12 # more error for better fit at a certain point
13 # so we'll include 10 components
14
15 pdf("~/Documents/Git/WUSIL_textAnalysis/HW5pcaEmbedding.pdf")
16 plot(machPCA$rotation, pch='',
17       xlab="1st Principal Component", ylab="2nd Principal Component")
18 text(machPCA$rotation, labels=str_extract(machDTM$dimnames$Docs, "[[:digit:]]+"), cex= 0.7)
19 dev.off()
20
21 # c) looking at figure 4, it appears that the first two components
22 # are orthogonal to each other and that most documents tend
23 # toward zero along both dimensions
24 # find extreme docs (13, 112, 134; and 76)
25 # first component seems to be advice to the ruler
26 # w/ examples that use Romans frequently
27 # second compotent is discussing protecting a ruler's state

```

Figure 3: Scree plot of the variance explained by the addition of each component.

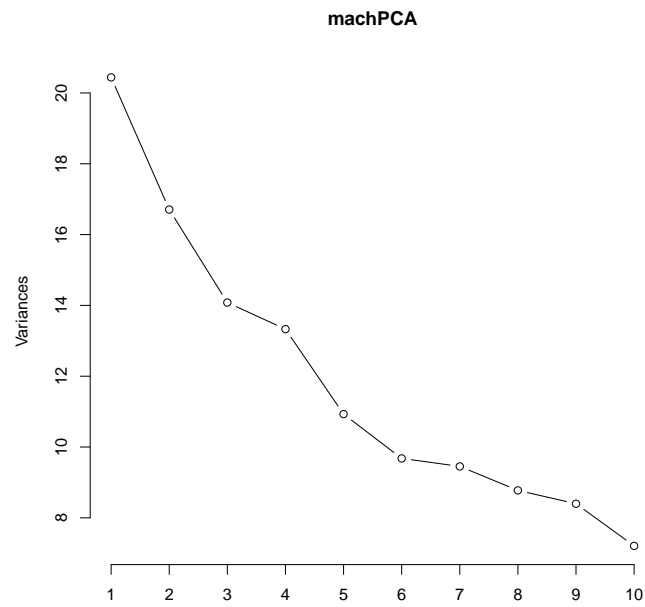

Figure 4: Projection of documents on the first two principal components.

- 3) An alternative method—discussed at the end of the seventh lecture—is multidimensional scaling (MDS). Classic MDS attempts to preserve distances between objects in a low dimensional scaling.
- a) Calculate the Euclidean distance between each document using \mathbf{X}^* . Call this matrix $\mathbf{D}(\mathbf{X}^*)$ (Hint: use R's built in function `dist`)
 - b) Apply the classic MDS to $\mathbf{D}(\mathbf{X}^*)$ using the R function `cmdscale`. That is, execute the code

```
mds_scale<- cmdscale(DISTANCE_MATRIX, k = 2)
```
 - c) Apply PCA to \mathbf{X}^* , but this time do not use `prcomp`'s scaling option. That is, use `prcomp` with `scale = F`.
 - d) Compare the first dimension of the output from classic MDS to the first dimension of the embedding from principal components. What is the correlation between the embeddings?
 - d) Now use `dist` to create a distance matrix using the `manhattan` metric, apply Classic multidimensional scaling to the distance matrix based on manhattan distance, and compare the first dimension of this embedding to the first dimension from PCA. What is the correlation?
 - e) What do you conclude about the relationship between PCA and MDS?
